

# BAYESIAN NETWORKS

## CHAPTER 14.1–4

# Outline

- ◇ Syntax
- ◇ Semantics
- ◇ Exact inference by enumeration
- ◇ Exact inference by variable elimination

# Bayesian networks

A simple, graphical notation for conditional independence assertions  
and hence for compact specification of full joint distributions

Syntax:

- a set of nodes, one per variable

- a directed, acyclic graph (link  $\approx$  “directly influences”)

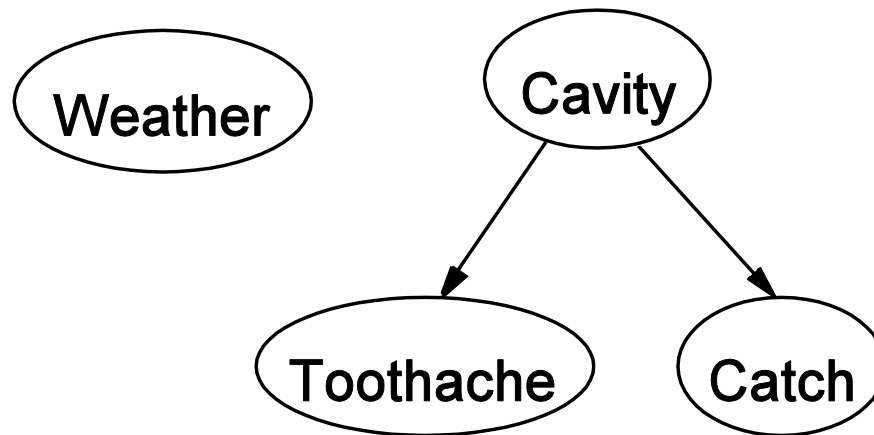

- a conditional distribution for each node given its parents:

$$P(X_i | \text{Parents}(X_i))$$

In the simplest case, conditional distribution represented as  
a **conditional probability table** (CPT) giving the  
distribution over  $X_i$  for each combination of parent values

## Example 1

Topology of network encodes conditional independence assertions:

*Weather* is independent of the other variables

*Toothache* and *Catch* are conditionally independent given *Cavity*

## Example 2

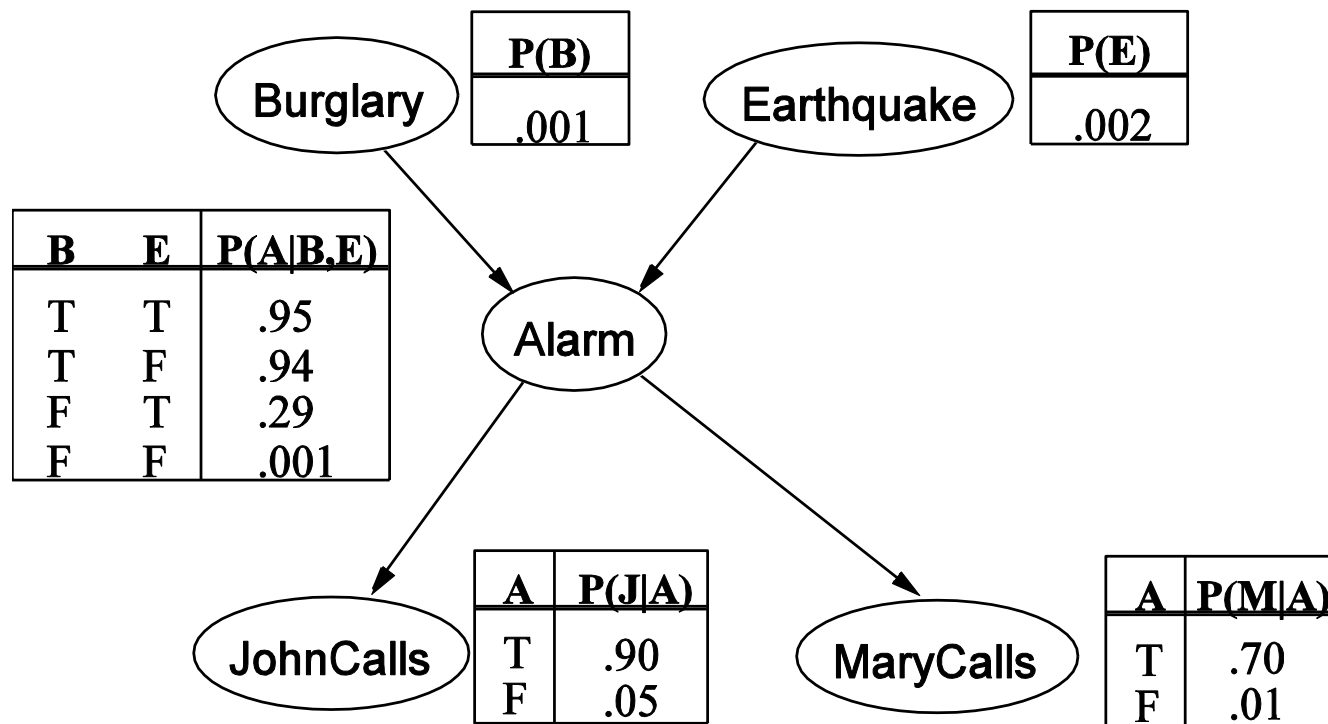

Scenario: I'm at work, neighbor John calls to say my alarm is ringing, but neighbor Mary doesn't call. Sometimes it's set off by minor earthquakes. Is there a burglar?

Variables: *Burglar*, *Earthquake*, *Alarm*, *JohnCalls*, *MaryCalls*

Network topology reflects “causal” knowledge:

- A burglar can set the alarm off
- An earthquake can set the alarm off
- The alarm can cause Mary to call
- The alarm can cause John to call

## Example 2 contd.

# Compactness

A CPT for Boolean  $X_i$  with  $k$  Boolean parents has  $2^k$  rows for the combinations of parent values

Each row requires one number  $p$  for  $X_i = \text{true}$   
(the number for  $X_i = \text{false}$  is just  $1 - p$ )

If each variable has no more than  $k$  parents,  
the complete network requires  $O(n \cdot 2^k)$  numbers

I.e., grows linearly with  $n$ , vs.  $O(2^n)$  for the full joint distribution

For burglary net,  $1 + 1 + 4 + 2 + 2 = 10$  numbers (vs.  $2^5 - 1 = 31$ )

## Global semantics

**Global** semantics defines the full joint distribution as the product of the local conditional distributions:

$$P(x_1, \dots, x_n) = \prod_{i=1}^n P(x_i | \text{parents}(X_i))$$

e.g.,  $P(j \wedge m \wedge a \wedge \neg b \wedge \neg e)$

=

## Global semantics

**Global** semantics defines the full joint distribution as the product of the local conditional distributions:

$$P(x_1, \dots, x_n) = \prod_{i=1}^n P(x_i | \text{parents}(X_i))$$

e.g.,  $P(j \wedge m \wedge a \wedge \neg b \wedge \neg e)$

$$= P(j|a)P(m|a)P(a|\neg b, \neg e)P(\neg b)P(\neg e)$$

$$= 0.9 \times 0.7 \times 0.001 \times 0.999 \times 0.998$$

$$\approx 0.00063$$

# Local semantics

**Local** semantics: each node is conditionally independent of its nondescendants given its parents

# Constructing Bayesian networks

Need a method such that a series of locally testable assertions of conditional independence guarantees the required global semantics

1. Choose an ordering of variables  $X_1, \dots, X_n$
2. For  $i = 1$  to  $n$ 
  - add  $X_i$  to the network
  - select parents from  $X_1, \dots, X_{i-1}$  such that
$$\mathbf{P}(X_i | \text{Parents}(X_i)) = \mathbf{P}(X_i | X_1, \dots, X_{i-1})$$

This choice of parents guarantees the global semantics:

$$\begin{aligned}\mathbf{P}(X_1, \dots, X_n) &= \prod_{i=1}^n \mathbf{P}(X_i | X_1, \dots, X_{i-1}) \quad (\text{chain rule}) \\ &= \prod_{i=1}^n \mathbf{P}(X_i | \text{Parents}(X_i)) \quad (\text{by construction})\end{aligned}$$

## Example

Suppose we choose the ordering  $M, J, A, B, E$

$$P(J|M) = P(J)?$$

## Example

Suppose we choose the ordering  $M, J, A, B, E$

$P(J|M) = P(J)$ ? No

$P(A|J, M) = P(A|J)$ ?  $P(A|J, M) = P(A)$ ?

## Example

Suppose we choose the ordering  $M, J, A, B, E$

$P(J|M) = P(J)$ ? No

$P(A|J, M) = P(A|J)$ ?  $P(A|J, M) = P(A)$ ? No

$P(B|A, J, M) = P(B|A)$ ?

$P(B|A, J, M) = P(B)$ ?

## Example

Suppose we choose the ordering  $M, J, A, B, E$

$P(J|M) = P(J)$ ? No

$P(A|J, M) = P(A|J)$ ?  $P(A|J, M) = P(A)$ ? No

$P(B|A, J, M) = P(B|A)$ ? Yes

$P(B|A, J, M) = P(B)$ ? No

$P(E|B, A, J, M) = P(E|A)$ ?

$P(E|B, A, J, M) = P(E|A, B)$ ?

## Example

Suppose we choose the ordering  $M, J, A, B, E$

$P(J|M) = P(J)$ ? No

$P(A|J, M) = P(A|J)$ ?  $P(A|J, M) = P(A)$ ? No

$P(B|A, J, M) = P(B|A)$ ? Yes

$P(B|A, J, M) = P(B)$ ? No

$P(E|B, A, J, M) = P(E|A)$ ? No

$P(E|B, A, J, M) = P(E|A, B)$ ? Yes

## Example contd.

Deciding conditional independence is hard in noncausal directions  
(symptoms  $\rightarrow$  causes)

Causal models (causes  $\rightarrow$  symptoms) and conditional independence  
seem easier for humans!

Assessing conditional probabilities is hard in noncausal directions

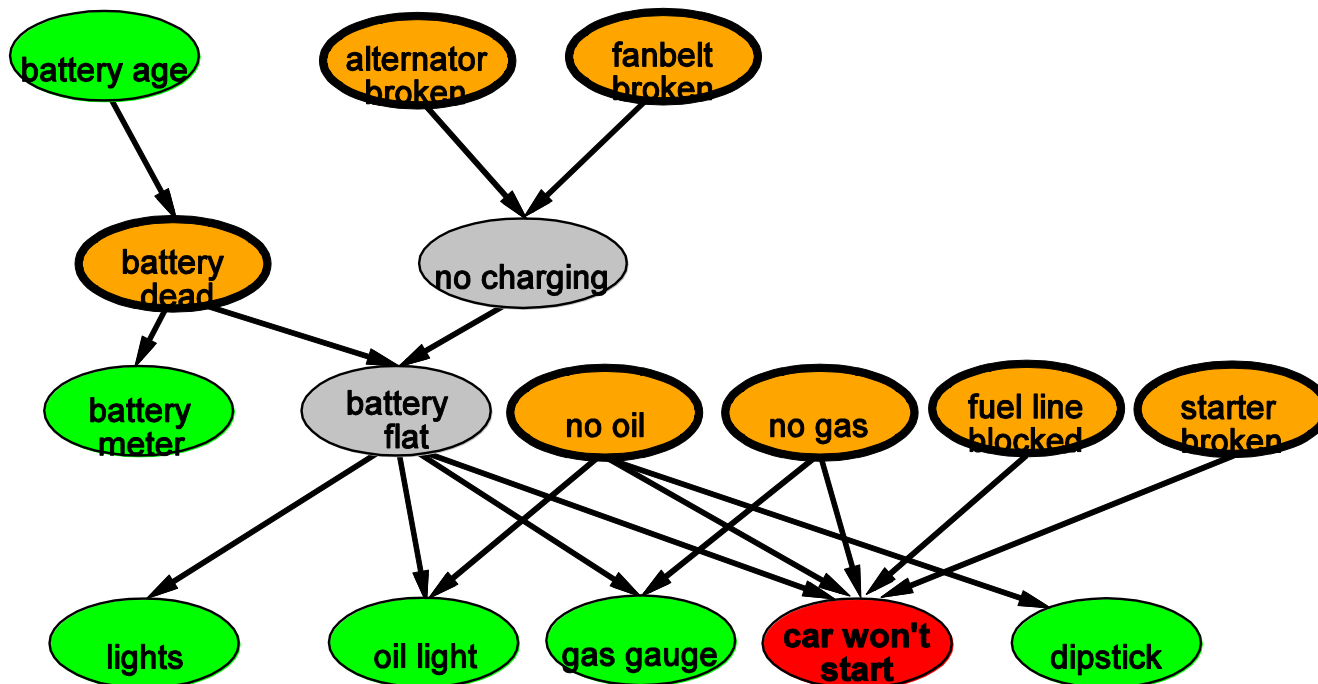

Network is less compact:  $1 + 2 + 4 + 2 + 4 = 13$  numbers needed

## Example: Car diagnosis

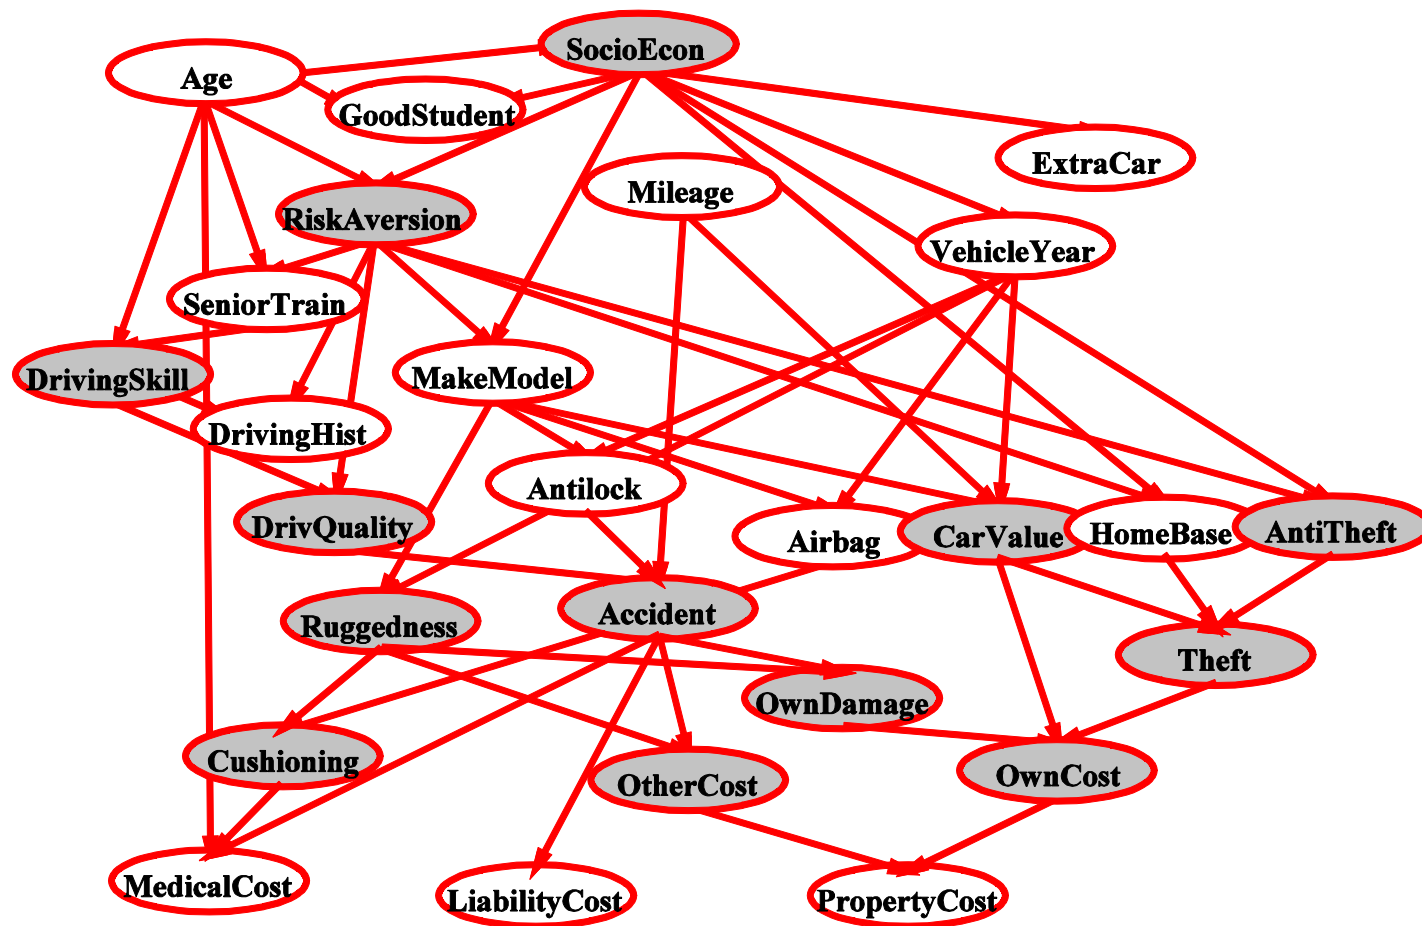

Initial evidence: car won't start

Testable variables (green), "broken, so fix it" variables (orange)

Hidden variables (gray) ensure sparse structure, reduce parameters

## Example: Car insurance

# Inference tasks

Simple queries: compute posterior marginal  $\mathbf{P}(X_i|\mathbf{E} = E)$

e.g.,  $P(\text{NoGas} | \text{Gauge} = \text{empty}, \text{Lights} = \text{on}, \text{Starts} = \text{false})$

Conjunctive queries:  $\mathbf{P}(X_i, X_j | \mathbf{E} = E) = \mathbf{P}(X_i | \mathbf{E} = E) \mathbf{P}(X_j | X_i, \mathbf{E} = E)$

Value of information: which evidence to seek next?

Sensitivity analysis: which probability values are most critical?

Explanation: why do I need a new starter motor?

We focus on **simple** and **conjunctive** queries

# Inference by enumeration

Slightly intelligent way to sum out variables from the joint without actually constructing its explicit representation

Simple query on the burglary network:

$$\begin{aligned} & \mathbf{P}(B|j, m) \\ &= \mathbf{P}(B, j, m) / P(j, m) \\ &= \alpha \mathbf{P}(B, j, m) \\ &= \alpha \sum_e \sum_a \mathbf{P}(B, e, a, j, m) \end{aligned}$$

Rewrite full joint entries using product of CPT entries:

$$\begin{aligned} & \mathbf{P}(B|j, m) \\ &= \alpha \sum_e \sum_a \mathbf{P}(B) P(e) \mathbf{P}(a|B, e) P(j|a) P(m|a) \\ &= \alpha \mathbf{P}(B) \sum_e P(e) \sum_a \mathbf{P}(a|B, e) P(j|a) P(m|a) \end{aligned}$$

Recursive depth-first enumeration:  $O(n)$  space,  $O(d^n)$  time

# Evaluation tree

Enumeration is inefficient: repeated computation  
 e.g., computes  $P(j|a)P(m|a)$  for each value of  $e$

# Inference by variable elimination

Variable elimination: carry out summations right-to-left, storing intermediate results (**factors**) to avoid recomputation

$$\begin{aligned} \mathbf{P}(B|j, m) &= \alpha \underbrace{\mathbf{P}(B)}_B \underbrace{\sum_e P(e)}_{\bar{E}} \underbrace{\sum_a \mathbf{P}(a|B, e)}_A \underbrace{P(j|a)}_J \underbrace{P(m|a)}_M \\ &= \alpha \mathbf{P}(B) \sum_e P(e) \sum_a \mathbf{P}(a|B, e) P(j|a) f_M(a) \\ &= \alpha \mathbf{P}(B) \sum_e P(e) \sum_a \mathbf{P}(a|B, e) f_J(a) f_M(a) \\ &= \alpha \mathbf{P}(B) \sum_e P(e) \sum_a f_A(a, b, e) f_J(a) f_M(a) \\ &= \alpha \mathbf{P}(B) \sum_e P(e) f_{\bar{A}JM}(b, e) \text{ (sum out } A) \\ &= \alpha \mathbf{P}(B) f_{\bar{E}\bar{A}JM}(b) \text{ (sum out } E) \\ &= \alpha f_B(b) \times f_{\bar{E}\bar{A}JM}(b) \end{aligned}$$

## Variable elimination: Basic operations

**Summing out** a variable from a product of factors:

move any constant factors outside the summation

add up submatrices in pointwise product of remaining factors

$$\sum_x f_1 \times \cdots \times f_k = f_1 \times \cdots \times f_i \sum_x f_{i+1} \times \cdots \times f_k = f_1 \times \cdots \times f_i \times f_{\bar{X}}$$

assuming  $f_1, \dots, f_i$  do not depend on  $X$

**Pointwise product** of factors  $f_1$  and  $f_2$ :

$$\begin{aligned} f_1(x_1, \dots, x_j, y_1, \dots, y_k) \times f_2(y_1, \dots, y_k, z_1, \dots, z_l) \\ = f(x_1, \dots, x_j, y_1, \dots, y_k, z_1, \dots, z_l) \end{aligned}$$

e.g.,  $f_1(a, b) \times f_2(b, c) = f(a, b, c)$

## Irrelevant variables

Consider the query  $P(\text{JohnCalls} | \text{Burglary} = \text{true})$

$$P(J|b) = \alpha P(b) \sum_e P(e) \sum_a P(a|b, e) P(J|a) \sum_m P(m|a)$$

Sum over  $m$  is identically 1;  $M$  is **irrelevant** to the query

Thm 1:  $Y$  is irrelevant unless  $Y \in \text{Ancestors}(\{X\} \cup \mathcal{E})$

Here,  $X = \text{JohnCalls}$ ,  $\mathcal{E} = \{\text{Burglary}\}$ , and  
 $\text{Ancestors}(\{X\} \cup \mathcal{E}) = \{\text{Alarm}, \text{Earthquake}\}$   
so  $\text{MaryCalls}$  is irrelevant

## Summary

Bayes nets provide a natural representation for (causally induced) conditional independence

Topology + CPTs = compact representation of joint distribution

Generally easy for (non)experts to construct

Exact inference by enumeration

Exact inference by variable elimination

Examples of skills expected:

- ◇ Formulate a belief network for a given problem domain
- ◇ Derive expression for joint probability distribution for given belief network
- ◇ Use inference by enumeration to answer a query about simple or conjunctive queries on a given belief network
