PROBLEM SOLVING AND SEARCH

Chapter 3, Sections 1–4

Outline

- \Diamond Problem-solving agents
- ♦ Problem types
- Problem formulation
- ♦ Example problems
- ♦ Basic search algorithms

Problem-solving agents

Restricted form of general agent:

```
function SIMPLE-PROBLEM-SOLVING-AGENT(p) returns an action inputs: p, a percept static: s, an action sequence, initially empty state, some description of the current world state g, a goal, initially null problem, a problem formulation state \leftarrow \text{UPDATE-STATE}(state, p) if s is empty then g \leftarrow \text{FORMULATE-GOAL}(state) problem \leftarrow \text{FORMULATE-PROBLEM}(state, g) s \leftarrow \text{SEARCH}(problem) action \leftarrow \text{RECOMMENDATION}(s, state) s \leftarrow \text{REMAINDER}(s, state) return action
```

Note: this is *offline* problem solving.

Online problem solving involves acting without complete knowledge of the problem and solution.

Example: Romania

On holiday in Romania; currently in Arad. Flight leaves tomorrow from Bucharest

Formulate goal:

be in Bucharest

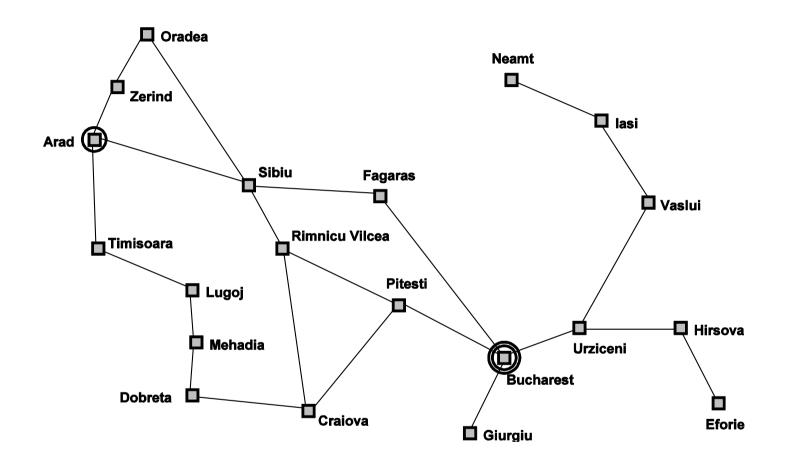

Formulate problem:

states: various cities operators: drive between cities

Find solution:

sequence of cities, e.g., Arad, Sibiu, Fagaras, Bucharest

Example: Romania

Single-state problem formulation

A *problem* is defined by four items:

```
\begin{array}{ll} \underline{nitial\ state} & \text{e.g., "at Arad"} \\ \underline{actions} \text{ (or } \underline{successor\ function\ } S(x)\text{)} \\ & \text{e.g., Arad} \rightarrow \mathsf{Zerind} & \mathsf{Arad} \rightarrow \mathsf{Sibiu} & \text{etc.} \\ \underline{goal\ test}, \text{ can be} \\ & \underline{explicit}, \text{ e.g., } x = \text{"at Bucharest"} \\ & \underline{implicit}, \text{ e.g., } Checkmate \text{ in chess} \\ \underline{path\ cost} \text{ (additive)} \\ & \text{e.g., sum of distances, number of actions executed, etc.} \end{array}
```

A solution is a sequence of actions leading from the initial state to a goal state

Note: we sometimes refer to actions as "operators"

Selecting a state space

Real world is absurdly complex

 \Rightarrow state space must be abstracted for problem solving

(Abstract) state = set of real states

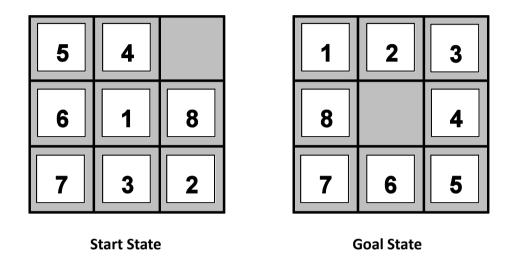

(Abstract) action = complex combination of real actions e.g., "Arad \rightarrow Zerind" represents a complex set of possible routes, detours, rest stops, etc.

For guaranteed realizability, \underline{any} real state "in Arad" must get to some real state "in Zerind"

(Abstract) solution = set of real paths that are solutions in the real world

Each abstract action should be "easier" than the original problem!

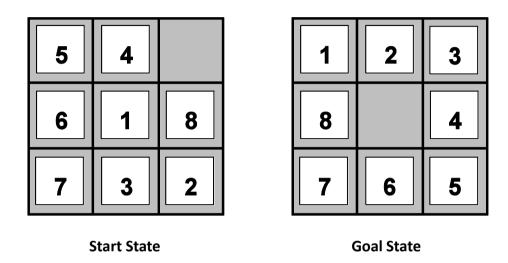

Example: The 8-puzzle

states??
actions??
goal test??
path cost??

[Note: optimal solution of n-Puzzle family is NP-hard]

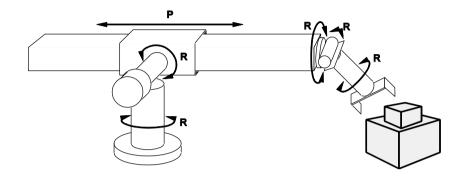

Example: The 8-puzzle

states??: integer locations of tiles (ignore intermediate positions)
actions??: move blank left, right, up, down (ignore unjamming etc.)
goal test??: = goal state (given)
path cost??: 1 per move

[Note: optimal solution of n-Puzzle family is NP-hard]

Example: robotic assembly

states??: real-valued coordinates of
 robot joint angles
 parts of the object to be assembled

actions??: continuous motions of robot joints

goal test??: complete assembly with no robot included!

path cost??: time to execute

Search algorithms

Basic idea:

offline, simulated exploration of state space
by generating successors of already-explored states

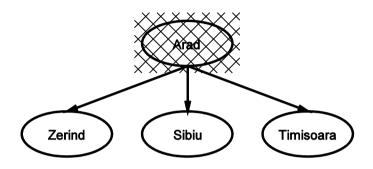

(a.k.a. expanding states)

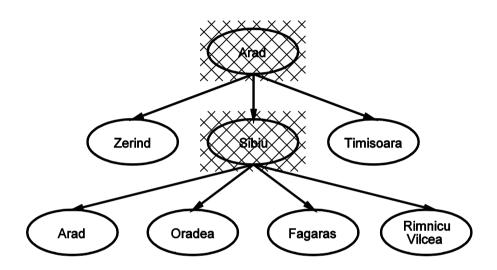

function General-Search (problem, strategy) returns a solution, or failure initialize the search tree using the initial state of problem loop do

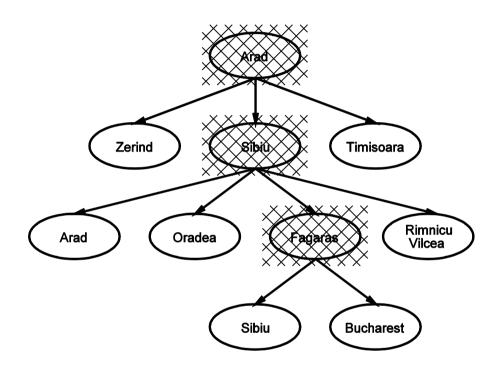

if there are no candidates for expansion then return failure choose a leaf node for expansion according to strategy

if the node contains a goal state then return the corresponding solution else expand the node and add the resulting nodes to the search tree end

Implementation of search algorithms

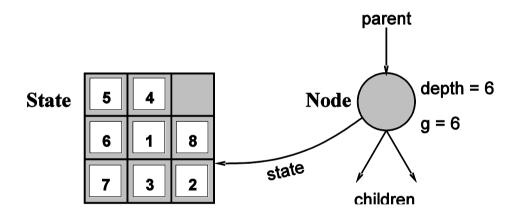

```
function General-Search (problem, Queuing-Fn) returns a solution, or failure nodes \leftarrow \text{Make-Queue}(\text{Make-Node}(\text{Initial-State}[problem])) loop do

if nodes is empty then return failure node \leftarrow \text{Remove-Front}(nodes)

if \text{Goal-Test}[problem] applied to \text{State}(node) succeeds then return node nodes \leftarrow \text{Queuing-Fn}(nodes, \text{Expand}(node, \text{Operators}[problem])) end
```

Implementation contd: states vs. nodes

A state is a (representation of) a physical configuration A node is a data structure constituting part of a search tree includes parent, children, depth, path cost g(x) States do not have parents, children, depth, or path cost!

The EXPAND function creates new nodes, filling in various fields and using OPERATORS (or ACTIONS) of problem to create the corresponding states.

Search strategies

A strategy is defined by picking the order of node expansion

Strategies are evaluated along the following dimensions:

completeness—does it always find a solution if one exists?

time complexity—number of nodes generated/expanded

space complexity—maximum number of nodes in memory optimality—does it always find a least-cost solution?

Time and space complexity are measured in terms of b—maximum branching factor of the search tree d—depth of the least-cost solution m—maximum depth of the state space (may be ∞)

Uninformed search strategies

Uninformed strategies use only the information available in the problem definition

Breadth-first search

Uniform-cost search

Depth-first search

Depth-limited search

Iterative deepening search

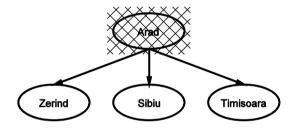

Expand shallowest unexpanded node

Implementation:

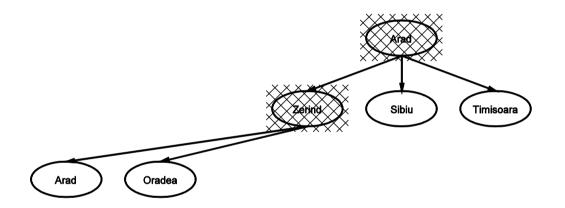

Expand shallowest unexpanded node

Implementation:

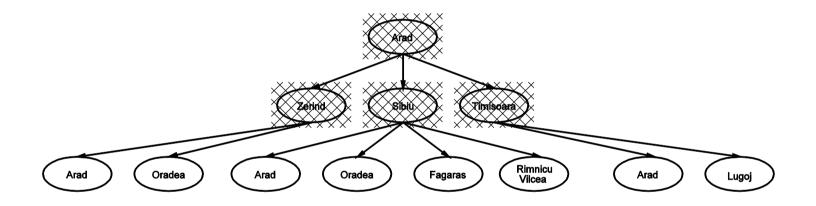

Expand shallowest unexpanded node

Implementation:

Expand shallowest unexpanded node

Implementation:

Properties of breadth-first search

Complete??

Time??

Space??

Optimal??

Properties of breadth-first search

Complete?? Yes (if b is finite)

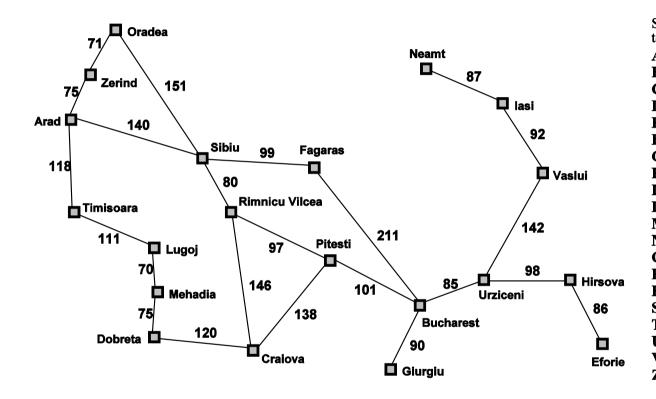

<u>Time</u>?? $1+b+b^2+b^3+\ldots+b^d=O(b^d)$, i.e., exponential in d

Space?? $O(b^d)$ (keeps every node in memory)

Optimal?? Yes (if cost = 1 per step); not optimal in general

Space is the big problem; can easily generate nodes at 1MB/sec so 24hrs = 86GB.

Romania with step costs in km

Straight-line distand o Bucharest	ce

Expand least-cost unexpanded node

Implementation:

 $\mathrm{QueueIngFn} = \mathsf{insert}$ in order of increasing path cost

Expand least-cost unexpanded node

Implementation:

 $\mathrm{QueueINGFN} = \text{insert}$ in order of increasing path cost

Expand least-cost unexpanded node

Implementation:

 $\mathrm{QueueINGFN} = \text{insert}$ in order of increasing path cost

Expand least-cost unexpanded node

Implementation:

 $\mathrm{QueueINGFN} = \text{insert}$ in order of increasing path cost

Properties of uniform-cost search

Complete?? Yes, if step cost $\geq \epsilon$

 $\underline{\operatorname{Time}} ?? \ \# \ \text{of nodes with} \ g \leq \ \operatorname{cost} \ \text{of optimal solution}$

Space?? # of nodes with $g \leq \cos t$ of optimal solution

Optimal?? Yes

Expand deepest unexpanded node

Implementation:

 $\ensuremath{\mathrm{QUEUEINGFN}} = \ensuremath{\mathsf{insert}}$ successors at front of queue

Expand deepest unexpanded node

Implementation:

 $\ensuremath{\mathrm{QUEUEINGFN}} = \ensuremath{\mathsf{insert}}$ successors at front of queue

Expand deepest unexpanded node

Implementation:

 $\ensuremath{\mathrm{QUEUEINGFN}} = \ensuremath{\mathsf{insert}}$ successors at front of queue

Expand deepest unexpanded node

Implementation:

 $\mathrm{QUEUEINGFN} = \mathsf{insert}$ successors at front of queue

I.e., depth-first search can perform infinite cyclic excursions

Need a finite, non-cyclic search space (or repeated-state checking)

Properties of depth-first search

Complete??

Time??

Space??

Optimal??

Properties of depth-first search

<u>Complete</u>?? No: fails in infinite-depth spaces, spaces with loops Modify to avoid repeated states along path ⇒ complete in finite spaces

<u>Time</u>?? $O(b^m)$: terrible if m is much larger than d but if solutions are dense, may be much faster than breadth-first

Space?? O(bm), i.e., linear space!

Optimal?? No

Depth-limited search

= depth-first search with depth limit $\it l$

Implementation:

Nodes at depth $\it l$ have no successors

Iterative deepening search

```
function Iterative-Deepening-Search(problem) returns a solution sequence inputs: problem, a problem  \begin{aligned} & \textbf{for } depth \leftarrow 0 \textbf{ to } \infty \textbf{ do} \\ & result \leftarrow \text{Depth-Limited-Search}(problem, depth) \\ & \textbf{if } result \neq \text{cutoff } \textbf{then } \textbf{return } result \\ & \textbf{end} \end{aligned}
```

Properties of iterative deepening search

Complete?? Yes

Time??
$$(d+1)b^0 + db^1 + (d-1)b^2 + \ldots + b^d = O(b^d)$$

 $\underline{\mathsf{Space}} ?? \ O(bd)$

Optimal?? Yes, if step cost = 1

Can be modified to explore uniform-cost tree

Bidirectional Search

Search simultaneously forwards from the start point, and backwards from the goal, and stop when the two searches meet in the middle.

Problems: generate predecessors; many goal states; efficient check for node already visited by other half of the search; and, what kind of search.

Properties of Bidirectional Search

Complete?? Yes

 $\underline{\mathsf{Time}}$?? $O(b^{\frac{d}{2}})$

Space?? $O(b^{\frac{d}{2}})$

Optimal?? Yes (if done with correct strategy - e.g. breadth first).

Summary

Problem formulation usually requires abstracting away real-world details to define a state space that can feasibly be explored

Variety of uninformed search strategies

Iterative deepening search uses only linear space and not much more time than other uninformed algorithms

Examples of skills expected:

- ♦ Formulate single-state search problem
- \Diamond Apply a search strategy to solve problem
- \Diamond Analyse complexity of a search strategy
